

Parallel-probe systematic-bias check: is the mean safe? $\delta = A(\text{wall probe}) - A(\text{far probe})$ (zero line = no bias)

δ per run (9373/170 – 9373/340) mm

mean $\delta \pm 95\%$ CI (9373/170 – 9373/340) mm

Top row: IN-side pair at 9373 mm (mar2026b, thesis scope 1.3–1.6 Hz). Bottom row: OUT-side pair at 12400 mm (Nov 2025, 0.5–2.0 Hz scope). Left panels: one marker per run. Right panels: group means with 95 % CI — error bars straddling zero = no detectable bias. One-sample t-tests ($p < 0.05$) flagged in the findings doc.
